

Ensuring Public Safety and Water Quality

Reducing pipe and plumbing corrosion.

This October, as part of our ongoing commitment to delivering safe, clean drinking water, MVWA will begin water treatment to help reduce corrosion of pipes and plumbing.

This added treatment helps form a thin, protective layer inside pipes to help prevent metals such as lead and copper from entering your drinking water.

MVWA worked with the New York State Department of Health and conducted three studies to determine the optimum corrosion control strategy for our water system.

The new treatment is designed to help MVWA maintain compliance with all state and federal drinking water standards and reflects our proactive approach to protecting both our water system and the health of our residents.

While water leaving the MVWA treatment plant is not a lead source, some homes have service lines and household plumbing that may contain lead. If your home was built before 1945, lead could be present in your pipes or fixtures.

In older homes, lead can leach into the water due to pipe corrosion. This water treatment is a small change with big benefits—and part of our broader commitment to delivering safe, high-quality water for everyone.

Quality water... for life.
